## Subjective Questions - Demonstration/Validation

1. What is the optimal value of alpha for ridge and lasso regression? What will be the changes in the model if you choose double the value of alpha for both ridge and lasso? What will be the most important predictor variables after the change is implemented?

Ans: The Optimal value of alpha for ridge is 5 and for lasso it is 0.0005

The optimum alpha is 5
The R2 Score of the model on the test dataset for optimum alpha is 0.7009502819383349
The MSE of the model on the test dataset for optimum alpha is 0.04988484385975613

And for Lasso:

```
# cross validation
folds = 11
model_cv = GridSearchCV(estimator = lasso, param_grid = params, scoring= 'r2', cv = folds, return_train_score=True, 'model_cv.fit(X_train_rfe3, y_train)

cv_results = pd.DataFrame(model_cv.cv_results_)
# plotting
plt.plot(cv_results['param_alpha'], cv_results['mean_train_score'])
plt.plot(cv_results['param_alpha'], cv_results['mean_test_score'])
plt.plot(cv_results['param_alpha'], cv_results['mean_test_score'])
plt.tylabel('alpha')
plt.tylabel('R2 Score and Alpha")
plt.tlegend(['train score', 'test score'], loc='upper right')
plt.show()

alpha = cv_results['param_alpha'].loc[cv_results['mean_test_score'].idxmax()]
print('The optimum alpha is',alpha)
lasso_final2 = Lasso(alpha=alpha,random_state=100)
lasso_final2.fit(X_train_rfe3,y_train)
lasso_coff2 = lasso_final2.coef_
y_test_pred = lasso_final2.predict(X_test_rfe3)
print('The R2 Score of the model on the test dataset for optimum alpha is',r2_score(y_test, y_test_pred))
print('The NCS of the model on the lest dataset for optimum alpha is', mean squared arror(y_lest_v_v_est_pred))
```

Fitting 11 folds for each of 11 candidates, totalling 121 fits

The optimum alpha is 0.0005The R2 Score of the model on the test dataset for optimum alpha is 0.7019242026257326The MSE of the model on the test dataset for optimum alpha is 0.04972238297620295

After using the double value of alpha for Ridge, i.e 10, we get the R2 score to 0.69 and the following coefficients changed.

The R2 Score of the model on the test dataset for doubled alpha is 0.6913997394905503 The MSE of the model on the test dataset for doubled alpha is 0.05147798135499183 The most important predictor variables are as follows:

For Lasso, after we used 0.001, we got R2 score as 0.68 and following coefficients changed.

```
lasso_double_coef = lasso_double.coef_
     y_test_pred = lasso_double.predict(X_test_rfe3)
print('The R2 Score of the model on the test dataset for doubled alpha is',r2_score(y_test, y_test_pred))
      print('The MSE of the model on the test dataset for doubled alpha is', mean_squared_error(y_test, y_test_pred))
     lasso_double_coeff = pd.DataFrame(np.atleast_2d(lasso_double_coef),columns=X_train_rfe3.columns)
lasso_double_coeff = lasso_double_coeff.T
      lasso double coeff.rename(columns={0: 'Lasso Doubled Alpha Co-Efficient'},inplace=True)
      lasso_double_coeff.sort_values(by=['Lasso_Doubled_Alpha_Co-Efficient'], ascending=False,inplace=True)
      print('The most important predictor variables are as follows:')
     lasso_double_coeff.head(20)
      The R2 Score of the model on the test dataset for doubled alpha is 0.6891077996505619
      The MSE of the model on the test dataset for doubled alpha is 0.0518603026017559
      The most important predictor variables are as follows:

```

The most important predictors after the changes will be: LotArea, Total\_porch\_sf, BsmtQual\_Ex, MasVnrType\_Stone and the rest as shown above.

2. You have determined the optimal value of lambda for ridge and lasso regression during the assignment. Now, which one will you choose to apply and why?

The optimal value of Alpha for Ridge is 5 and Lasso is 0.001

MSE for Ridge is: 0.04988484385975613 MSE for Lasso is: 0.04972238297620295

Since, MSE for Lasso is small and since it's helpful in feature reduction and selection, I would choose Lasso Regression.

3. After building the model, you realised that the five most important predictor variables in the lasso model are not available in the incoming data. You will now have to create another model excluding the five most important predictor variables. Which are the five most important predictor variables now?

The top 5 most important predictor variables after building the model again are: LotFrontage
Total\_porch\_sf
HouseStyle\_2.5Unf
HouseStyle\_2.5Fin
Neighbourhood\_Veenker

4. How can you make sure that a model is robust and generalisable? What are the implications of the same for the accuracy of the model and why?

As Per, Occam's Razor— given two models that show similar 'performance' in the finite training or test

data, we should pick the one that makes fewer on the test data due to following reasons:-

- Simpler models are usually more 'generic' and are more widely applicable
- Simpler models require fewer training samples for effective training than the more complex ones and hence are easier to train.
- Simpler models are more robust.
- Complex models tend to change wildly with changes in the training data set
- Simple models have low variance, high bias and complex models have low bias, high variance
- Simpler models make more errors in the training set. Complex models lead to overfitting —
  - they work very well for the training samples, fail miserably when applied to other test samples

Therefore, to make the model more robust and generalizable, make the model simple but not simpler which will not be of any use.

Regularization can be used to make the model simpler. Regularization helps to strike the delicate balance between keeping the model simple and not making it too naive to be of any use. For regression, regularization involves adding a regularization term to the cost that adds up the absolute values or the squares of the parameters of the model.

Also, Making a model simple leads to Bias-Variance Trade-off:

- A complex model will need to change for every little change in the dataset and hence is very unstable and extremely sensitive to any changes in the training data.
- A simpler model that abstracts out some pattern followed by the data points given is unlikely to change wildly even if more points are added or removed.
